

# Half-Sandwich Pentamethylcyclopentadienyl Oxo and Alkoxo Complexes of Tantalum. Synthesis and Characterisation of $(\eta\text{-C}_5\text{Me}_5)\text{Ta}(\text{O})\text{Cl}_2$ †

Vernon C. Gibson and Terence P. Kee

Department of Chemistry, University Science Laboratories, South Road, Durham DH1 3LE, U.K.

$(\eta\text{-C}_5\text{Me}_5)\text{Ta}(\text{O})\text{Cl}_2$  has been isolated in 40% yield from the reaction of  $(\eta\text{-C}_5\text{Me}_5)\text{TaCl}_2(\text{PMe}_3)_2$  with carbon dioxide; the mono-alkoxides  $(\eta\text{-C}_5\text{Me}_5)\text{TaCl}_3(\text{OR})$  ( $\text{R} = \text{Me}, \text{Et}$ ) and the oxo-bridged dimer  $[(\eta\text{-C}_5\text{Me}_5)\text{TaCl}_3]_2(\text{O})$  are obtained by treatment of  $(\eta\text{-C}_5\text{Me}_5)\text{TaCl}_4$  with  $\text{Me}_3\text{SiOR}$  ( $\text{R} = \text{Me}, \text{Et}$ ) and  $(\text{Me}_3\text{Si})_2\text{O}$  respectively.

There is much current interest in the reactivity of half-sandwich transition metal oxides and alkoxides since they provide soluble model species through which to probe the chemistry of metal–oxygen fragments relevant to heterogeneous oxidation catalysis. The first half-sandwich organometal oxide to be described was  $(\eta\text{-C}_5\text{H}_5)\text{V}(\text{O})\text{Cl}_2$ , reported by Fischer<sup>1</sup> as long ago as 1958. Despite considerable recent progress in the synthesis of group 6 organometal oxides,<sup>2</sup> and extensive studies on the rhenium system  $\text{Cp}^*\text{ReO}_3$ <sup>3</sup> ( $\text{Cp}^* = \text{C}_5\text{Me}_5$ ), half-sandwich oxo complexes of the heavier group 5 metals have proved particularly elusive.

Here, we describe the synthesis and characterisation of  $\text{Cp}^*\text{Ta}(\text{O})\text{Cl}_2$  (**1**), the first heavy metal analogue of Fischer's vanadium complex, along with half-sandwich mono-alkoxides of the type  $\text{Cp}^*\text{TaCl}_3(\text{OR})$  [ $\text{R} = \text{Me}$ , (**3**);  $\text{Et}$ , (**4**)] and the oxo-bridged dimer  $[\text{Cp}^*\text{TaCl}_3]_2(\text{O})$  (**5**). All products have been characterised by mass spectrometry, i.r. and n.m.r. spectroscopies,† and give satisfactory elemental analyses.

Treatment of the paramagnetic  $d^2$  complex  $\text{Cp}^*\text{TaCl}_2(\text{PMe}_3)_2$ <sup>4</sup> with 1 atm. carbon dioxide in toluene at room temperature for 12 h gives yellow crystalline (**1**) in 40% yield (equation 1). Compound (**1**) arises by oxygen abstraction from  $\text{CO}_2$  and precipitates from a red–brown supernatant solution which is found to contain  $\text{Cp}^*\text{TaCl}_2(\text{CO})_2(\text{PMe}_3)$  (**2**). Compound (**2**) is formed by reaction of  $\text{Cp}^*\text{TaCl}_2(\text{PMe}_3)_2$  with the

carbon monoxide by-product and has been characterised by comparison with data from an authentic sample.<sup>4</sup>

Compound (**1**) is moisture sensitive and sublimes at 180 °C ( $5 \times 10^{-6}$  torr); it is partially soluble in aromatic solvent. Its poor solubility has prevented accurate molecular weight determinations. However, a low resolution mass spectrum gives an envelope at  $m/z$  805 ( $^{35}\text{Cl}$ ) consistent with a dimeric formulation (no higher mass fragments are observed) and the i.r. spectrum shows a strong band at 675  $\text{cm}^{-1}$  indicating the presence of bridging oxo ligands. Thus,  $\text{Cp}^*\text{Ta}(\text{O})\text{Cl}_2$  (**1**) may be reasonably formulated as an oxo-bridged dimer (a representation with *trans*  $\text{Cp}^*$  ligands is illustrated in Figure 1).

Compounds (**3**) and (**4**) have been prepared by exploiting the reaction between transition metal halides and silyl ethers<sup>5</sup> (equations 2 and 3). Thus, treatment of  $\text{Cp}^*\text{TaCl}_4$  with  $\text{Me}_3\text{SiOR}$  ( $\text{R} = \text{Me}, \text{Et}$ ) at 70 °C in dichloroethane affords the yellow crystalline monoalkoxides  $\text{Cp}^*\text{TaCl}_3(\text{OR})$  [ $\text{R} = \text{Me}$ , (**3**);  $\text{Et}$ , (**4**)] in high yield according to Scheme 1.

† First presented at the Los Angeles A.C.S. meeting, September 25th–30th, 1988.

‡ Selected spectroscopic data for (**1**):  $^1\text{H}$  n.m.r. ( $\text{C}_6\text{D}_6$ , 250 MHz, 298 K)  $\delta$  2.22 (s,  $\text{C}_5\text{Me}_5$ ). I.r. ( $\text{CsI}$ , Nujol,  $\text{cm}^{-1}$ ): 1430 (m), 1070 (w), 1025 (m), 803 (w), 675 (s, br), 610 (w), 598 (m), 550 (m), 436 (w), 387 (s), 330 (s), 310 (s), 291 (s). CI mass spec. ( $m/z$ ,  $^{35}\text{Cl}$ ): 805 [ $M_2 - \text{H}$ ]<sup>+</sup>, 403 [ $M + \text{H}$ ]<sup>+</sup>. For (**2**):  $^1\text{H}$  n.m.r. ( $\text{CDCl}_3$ , 250 MHz, 298 K)  $\delta$  2.44 (s, 15H,  $\text{C}_5\text{Me}_5$ ), 4.57 (s, 3H,  $\text{OMe}$ );  $^{13}\text{C}\{^1\text{H}\}$  n.m.r. ( $\text{CDCl}_3$ , 62.9 MHz, 298 K)  $\delta$  128.53 (s,  $\text{C}_5\text{Me}_5$ ), 67.17 (s,  $\text{OCH}_3$ ), 12.84 (s,  $\text{C}_5\text{Me}_5$ ). I.r. ( $\text{CsI}$ , Nujol,  $\text{cm}^{-1}$ ): 1483 (m), 1435 (m), 1127 (s, br), 1041 (m), 1025 (m), 963 (w), 805 (w), 683 (w), 523 (m), 381 (m), 335 (s), 290 (s). For (**3**):  $^1\text{H}$  n.m.r. ( $\text{CDCl}_3$ , 250 MHz, 298 K)  $\delta$  1.37 [t, 3H,  $^3J(\text{HH})$  7.0 Hz,  $\text{OCH}_2\text{CH}_3$ ], 2.44 (s, 15H,  $\text{C}_5\text{Me}_5$ ), 4.84 [q, 2H,  $^3J(\text{HH})$  7.0 Hz,  $\text{OCH}_2\text{CH}_3$ ];  $^{13}\text{C}$  n.m.r. ( $\text{CDCl}_3$ , 62.9 MHz, 298 K)  $\delta$  128.32 (s,  $\text{C}_5\text{Me}_5$ ), 76.20 [t,  $^1J(\text{CH})$  149.6 Hz,  $\text{OCH}_2\text{CH}_3$ ], 17.27 [q,  $^1J(\text{CH})$  127.2 Hz,  $\text{OCH}_2\text{CH}_3$ ], 12.96 [q,  $^1J(\text{CH})$  128.1 Hz,  $\text{C}_5\text{Me}_5$ ]. I.r. ( $\text{CsI}$ , Nujol,  $\text{cm}^{-1}$ ): 1115 (s, br), 1082 (s), 1030 (m), 1020 (m), 940 (m), 807 (w), 800 (w), 720 (w), 563 (m), 376 (m), 340 (s), 300 (m), 286 (m, sh).

Compounds (**3**) and (**4**) may be heated at 100 °C for several hours without further elimination of  $\text{RCl}$ . However, upon warming  $\text{Cp}^*\text{TaCl}_4$  with hexamethyldisiloxane at 70 °C in  $\text{CH}_3\text{CN}$ , elimination of two equivs. of  $\text{Me}_3\text{SiCl}$  occurs to afford the oxo-bridged dimer  $[\text{Cp}^*\text{TaCl}_3]_2(\text{O})$  (**5**). Compound (**5**) has been isolated previously in 8% yield by hydrolysis of

**Scheme 1.** Reagents and conditions: i,  $\text{Me}_3\text{SiOR}$ ,  $\text{C}_2\text{H}_4\text{Cl}_2$ , 70 °C, 18 h,  $-\text{Me}_3\text{SiCl}$ ; ii,  $(\text{Me}_3\text{Si})_2\text{O}$ ,  $\text{CH}_3\text{CN}$ , 70 °C, 3.5 h,  $-\text{Me}_3\text{SiCl}$ .

$\text{Cp}^*\text{TaCl}_4$ .<sup>6</sup>  $\text{Cp}^*\text{Ta}(\text{O})\text{Cl}_2$  is not produced under these conditions, most probably due to its reactivity towards  $\text{Me}_3\text{SiCl}$ . For example a sample of (1) treated with two equivs. of  $\text{Me}_3\text{SiCl}$  at  $70^\circ\text{C}$  in  $\text{C}_6\text{D}_6$  deposits (5) and gives signals in the  $^1\text{H}$  n.m.r. spectrum attributable to small amounts of two, as yet, uncharacterised siloxide species.  $\text{Cp}^*\text{Ta}(\text{O})\text{Cl}_2$  (1) is also surprisingly unstable in solution, slowly converting above room temperature to (5) and a species which gives a single  $\text{Cp}^*$  proton resonance at  $\delta$  2.15 ( $\text{C}_6\text{D}_6$ ).<sup>§</sup> These observations may explain why the heavier group 5 derivatives have proved somewhat elusive, but nevertheless augurs well for the reactivity of oxygen atoms in these environments. Studies are now being directed towards assessing the influence of competitive metal–ligand  $\pi$ -interactions upon the nature of the bonding and reactivity of the oxo ligand in (1) and its analogues.

<sup>§</sup> Note added in proof. A crystal structure (ref. 7) of this product (crystallised as a 1 : 1 toluene solvate) shows it to be the asymmetrically-bridged trinuclear cluster,  $\text{Cp}_3^*\text{Ta}_3\text{O}_4\text{Cl}_4$  possessing a terminal chloride on each Ta, 3 edge-bridging oxo ligands, and a  $\mu_3$ -oxo group capping the  $\text{Ta}_3$  face. The remaining chloride ligand bridges two of the tantalum atoms. A partial structure determination on this compound has been reported in ref. 6. The single  $\delta$  2.15 resonance in  $\text{C}_6\text{D}_6$  arises due to coincidental overlap of the  $\text{Cp}^*$  methyl resonances.

We thank the S.E.R.C. for a grant (to V. C. G.) and a studentship (to T. P. K.).
