## ABSTRACT

A cyclic porphyrin trimer has been synthesized which has a high affinity for fullerenes. It forms 1:1 complexes with C<sub>60</sub> and C<sub>70</sub> with association constants of  $2 \times 10^6$  and  $2 \times 10^8$  M<sup>-1</sup>, respectively, in toluene. Its affinities for C<sub>86</sub> and La@C<sub>82</sub> are too strong to measure by fluorescence titration. The solvent dependence of the association constants shows that solvation of both the guest and the host influence the binding strength.

Paramagnetic endohedral fullerenes are well-known for their long coherence times ( $T_2$ ); for example, N@C<sub>60</sub> has a  $T_2$  of 300  $\mu$ s, which is an order of magnitude longer than those of other molecular radicals.<sup>1</sup> This property makes them promising qubits for quantum information processing.<sup>2</sup> In order to develop materials for this application, we need a way of holding several endohedral fullerene units in precise spatial arrangements, so that the entanglement between their spins can be manipulated. A molecular framework functionalized with noncovalent fullerene receptors would be the ideal scaffold because it could bind the fullerene quantitatively at

the final stage of the synthesis, while scarcely perturbing the environment around the endohedral paramagnetic atom. Such receptors will need to have high affinities for fullerenes to achieve quantitative binding in dilute solution. Here we report the synthesis of a receptor designed for this application. A single phthalimide connection point is rigidly attached to the receptor, so that in the future several such receptors can be linked together to create multispin arrays with precise geometries. This receptor has a high binding affinity for C<sub>60</sub> in toluene, and the affinity increases by at least 2 orders of magnitude on moving to larger fullerenes (C<sub>70</sub>, C<sub>86</sub>, and La@C<sub>82</sub>). These results imply that receptor **1** will bind strongly to other endohedral fullerenes such as N@C<sub>60</sub>.

Among the wide range of receptors for fullerenes reported in the literature,<sup>3</sup> those based on porphyrins display the highest binding affinities.<sup>4,5</sup> Many structures with a single

porphyrin–fullerene interaction have been characterized in the solid state,<sup>4,6,7</sup> but these complexes readily dissociate in solution, and most solution-phase receptors utilize two or more porphyrin units.<sup>5,8–12</sup> We reasoned that a cyclic porphyrin trimer in which three porphyrins are preorganized to chelate to the same fullerene guest might provide very strong binding. No covalent macrocyclic receptors have previously been reported that exhibit this type of tridentate porphyrin–fullerene interaction, although 3:1 coordination geometries have been reported in solid-state complexes,<sup>7</sup> metal-coordinate self-assemblies,<sup>11</sup> and complexes of tripodal porphyrin trimers.<sup>12</sup> Four-coordinate complexes, in which two porphyrin dimers chelate to the same fullerene molecule have also been reported.<sup>13</sup>

Molecular mechanics calculations on a variety of potential receptors identified porphyrin trimer **1** as a promising target. In the calculated structure of the **1**·C<sub>60</sub> complex (Figure 1),

**Figure 1.** Calculated structure of the C<sub>60</sub>·**1** complex (MM+, Hyperchem 8.0). Distances shown from the centroid of the porphyrins to the centroid of the fullerene.

the distances from the centroid of the fullerene to the centroids of the three porphyrins are 6.42, 6.44, and 6.48 Å.

A search of the Cambridge Structural Database shows that the mean value of this C<sub>60</sub> centroid to porphyrin centroid parameter is  $6.28 \pm 0.08$  Å (mean for 21 zinc porphyrin C<sub>60</sub> interactions).<sup>14</sup> We calculate that the D<sub>3h</sub> symmetric analogue of receptor **1** with 3,3′-biphenyl links, at all three corners, would have a cavity centroid to porphyrin centroid distance of 5.91 Å, making it too small to accommodate C<sub>60</sub>. Thus the roles of the phthalimide unit in the design of **1** are to expand the cavity and to provide a rigid attachment point.

Cyclic porphyrin trimer **1** was synthesized by Sonogashira coupling of 3,4-diiodophthalimide **2**<sup>15</sup> and the alkyne-terminated linear porphyrin trimer **3** (Scheme 1). The linear trimer **4** was prepared by Suzuki coupling of porphyrins **5** and **7** and deprotected to give **3**. Porphyrin monomers **6** and **7** were obtained by statistical reaction of with dipyrromethane **8** with aldehydes **9** and **10**.<sup>16</sup> The most difficult part of this synthesis turned out to be preparation of the porphyrin bisboronic acid **5**. After testing several routes to this compound, it was obtained in 25% yield from **6** by palladium-catalyzed boronylation.

The <sup>1</sup>H NMR spectrum of the cyclic porphyrin trimer **1** confirms its C<sub>2v</sub> symmetry. Its purity and identity were established by <sup>1</sup>H NMR, <sup>13</sup>C NMR, <sup>1</sup>H–<sup>1</sup>H NOESY, GPC, MALDI-TOF MS, and UV–vis spectroscopy (see Supporting Information).

Boyd and co-workers have shown that fullerene–porphyrin interactions are highly solvent-dependent, and that the strengths of these interactions can be maximized by selecting solvents in which C<sub>60</sub> has a low solubility.<sup>9c</sup> Thus we chose to investigate the interaction of trimer **1** with C<sub>60</sub> in a variety of solvents covering a wide range of C<sub>60</sub> solubilities. UV–vis titrations were carried out in THF, cyclohexane, carbon tetrachloride, toluene, and *o*-dichlorobenzene. In all cases, the formation of a 1:1 complex with a red-shifted Soret band was detected.<sup>17,18</sup> A typical set of titration spectra is shown in Figure 2a, and the binding constants measured in these five solvents are summarized in Table 1.

The solubility data<sup>19</sup> provide a good measure of the ability of each solvent to solvate C<sub>60</sub>. As expected, the worst solvent (cyclohexane) gives the highest binding constant [ $(2.1 \pm 0.3) \times 10^7$  M<sup>−1</sup>], while the best solvent (*o*-dichlorobenzene) gives the lowest binding constant [ $(2.2 \pm 0.2) \times 10^4$  M<sup>−1</sup>]. However, THF and carbon tetrachloride do not fit the trend: they give weaker binding constants than expected based on

C <sub>60</sub>	toluene	$(1.6 \pm 0.7) \times 10^6$	2.8
C <sub>60</sub>	<i>o</i> -dichlorobenzene	$(2.2 \pm 0.2) \times 10^4$	27
C <sub>70</sub>	toluene	$(1.6 \pm 0.7) \times 10^8$	1.1
C <sub>86</sub>	toluene	$>10^9$	—
La@C <sub>82</sub>	toluene	$>10^9$	—

<sup>a</sup> All association constants were measured at 298 K; values for C<sub>60</sub> were measured by UV–vis titration, whereas those for the higher fullerenes were measured by fluorescence titration.

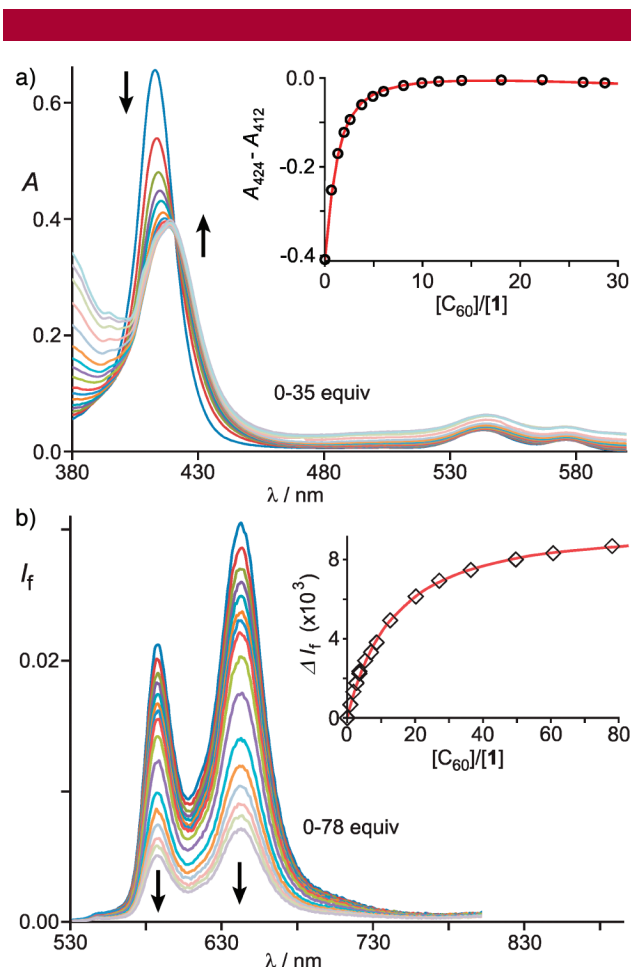

their C<sub>60</sub> solubility data, probably because they are good solvents for zinc porphyrin units.<sup>20</sup> The variation in binding constant with solvent reflects the strength of solvation of both the host and the guest.

This solvent study enabled us to identify toluene as the best compromise in terms of high association constant [(1.6

$\pm 0.7) \times 10^6 \text{ M}^{-1}$ ], satisfactory solubility of both components and ease of comparison with published work on other receptor–fullerene complexes. Preliminary experiments with the higher fullerenes (C<sub>70</sub>, C<sub>86</sub>, and La@C<sub>82</sub>) showed that their complexes with **1** in toluene are all too strong to quantify by UV–vis titration, so we switched technique to fluorescence titration to enable stronger association constants to be measured by working at lower concentrations. Binding to fullerenes quenches the fluorescence of the receptor (Figure 2b), presumably via photoinduced electron transfer from the receptor to the fullerene. The fluorescence titration of **1** with C<sub>60</sub> gave an association constant of  $(8.3 \pm 0.7) \times 10^5 \text{ M}^{-1}$ , which is acceptably close to the value from UV–vis titration. The results for the higher fullerenes are summarized in Table 1. The C<sub>70</sub>•**1** complex is 2 orders of magnitude more stable than C<sub>60</sub>•**1** (i.e.,  $K_{\text{C}_{70}}/K_{\text{C}_{60}} \approx 100$ ), while C<sub>86</sub>•**1** and La@C<sub>82</sub>•**1** are too stable to measure by fluorescence titration ( $K > 10^9 \text{ M}^{-1}$ ). Strong binding to C<sub>70</sub> and C<sub>86</sub> was confirmed by mass spectrometry: when a MALDI-TOF mass spectrum was recorded for an equimolar mixture of C<sub>60</sub>, C<sub>70</sub>, C<sub>86</sub>, and receptor **1**, peaks were observed for C<sub>70</sub>•**1** and C<sub>86</sub>•**1**, but not for C<sub>60</sub>•**1** (see Supporting Information).

Comparison with published work on other fullerene receptors<sup>8</sup> reveals that cyclic trimer **1** binds C<sub>60</sub> in toluene slightly more strongly than cyclic zinc porphyrin dimers, indicating that the presence of the third porphyrin unit has a small but positive influence on the affinity for C<sub>60</sub>. However, the cooperative effect of the third porphyrin becomes

(20) The data in Table 1 imply that 1 equiv of receptor **1** increases the solubility of C<sub>60</sub> in cyclohexane by a factor of  $1050 \pm 150$ . We have observed that the presence of **1** increases the solubility of C<sub>60</sub>, but we have not measured the solubility of the 1:1 complex. Other receptors have previously been reported to enhance the solubility of fullerenes; see: Pantos, G. D.; Wietor, J.-L.; Sanders, J. K. M. *Angew. Chem., Int. Ed.* **2007**, *46*, 2238–2240.

**Figure 2.** (a) Absorption spectral change of **1** ( $0.77 \mu\text{M}$ ) in toluene at 298 K upon titration with  $\text{C}_{60}$  ( $0\text{--}27 \mu\text{M}$ ), 10 mm path length. Inset: plot of  $(A_{424} - A_{412})$  against number of equivalents of  $\text{C}_{60}$ : circles = experimental data. (b) Fluorescence spectra during the titration of **1** ( $0.093 \mu\text{M}$ ) with  $\text{C}_{60}$  ( $0\text{--}7.2 \mu\text{M}$ ) in toluene at 298 K ( $\lambda_{\text{ex}} = 413 \text{ nm}$ ). Inset: plot of  $\Delta I_{615}$  against number of equivalents of  $\text{C}_{60}$ : diamonds = experimental data. All titrations were performed at constant receptor concentration.

dramatic with the higher fullerenes. The stability of the  $\text{C}_{70}\cdot\mathbf{1}$  complex is much higher than those of previously reported zinc porphyrin receptors (which typically have  $K_{\text{C}_{70}}/K_{\text{C}_{60}} \approx 10$ ).<sup>8,9</sup> We are not aware of previous binding results with  $\text{C}_{86}$  or endohedral fullerenes. Evidently, the greater size of

$\text{C}_{70}$ ,  $\text{C}_{86}$ , and  $\text{La}@\text{C}_{82}$  enables them to interact well with all three walls of the receptor. The electronic polarization of  $\text{La}@\text{C}_{82}$  may also contribute toward its strong binding.<sup>21</sup> The surprisingly large value of  $K_{\text{C}_{70}}/K_{\text{C}_{60}}$  for receptor **1** indicates that its cavity is slightly too large for binding  $\text{C}_{60}$ , as deduced above from molecular modeling and crystallographic data.

In conclusion, a cyclic trimer of porphyrins **1** has been synthesized, and its binding to  $\text{C}_{60}$  has been studied in a range of solvents. There is no clear trend relating the solubility of  $\text{C}_{60}$  in each solvent to the affinity of  $\text{C}_{60}$  for receptor **1** in that solvent, but desolvation of the host and of the guest is evidently important. The highest value for the binding constant to  $\text{C}_{60}$  is obtained in cyclohexane. Other fullerenes ( $\text{C}_{70}$ ,  $\text{C}_{86}$ , and  $\text{La}@\text{C}_{82}$ ) show very high binding constants to receptor **1** in toluene. The value of  $K$  for  $\text{C}_{70}\cdot\mathbf{1}$  is  $1 \times 10^8 \text{ M}^{-1}$ , which is substantially higher than those of previous receptors based on zinc porphyrins. The affinities for  $\text{C}_{86}$  and  $\text{La}@\text{C}_{82}$  are beyond the limit of the fluorescence titration techniques ( $K > 10^9 \text{ M}^{-1}$ ). To the best of our knowledge, this is the first report of binding of endohedral fullerenes to a molecular receptor.<sup>21</sup> It is well-known that metalloporphyrins such as those of rhodium(III) bind fullerenes much more strongly than zinc porphyrins,<sup>3,5,8b,13</sup> thus changing the metal in **1** should lead to even higher fullerene affinities. The high affinity for  $\text{La}@\text{C}_{82}$  displayed by receptor **1** in toluene indicates that covalently linked assemblies, decorated with multiple copies of this receptor, should be capable of complexing multiple spin-active fullerenes, providing a promising system for studying spin entanglement.
