## ABSTRACT

The facile reaction of [60]fullerene (C<sub>60</sub>) with various aldehydes or ketones in the presence of ferric perchlorate successfully afforded the rare C<sub>60</sub>-fused 1,3-dioxolanes. A possible reaction mechanism for the formation of the C<sub>60</sub>-fused 1,3-dioxolanes is proposed.

Since the availability of fullerenes in a macroscopic amount, various types of reactions for the functionalization of fullerenes have been discovered, and numerous fullerene products with wide structural diversities have been prepared.<sup>1</sup> However, fullerene-fused 1,3-dioxolane derivatives<sup>2–4</sup> have been relatively rare until now. Elemes et al. reported the

synthesis of the first fullerene-fused 1,3-dioxolane as one of the two products via the reaction of [60]fullerene (C<sub>60</sub>) with dimethyldioxirane.<sup>2a</sup> Wang et al. described the preparation of another C<sub>60</sub>-fused 1,3-dioxolane by the reaction of C<sub>60</sub> with PhCH<sub>2</sub>ONa-PhCH<sub>2</sub>OH under aerobic conditions.<sup>2b</sup> It should be noted that the latter methodology was only limited to benzoxide as the reaction of C<sub>60</sub> with other alkoxides gave fullerene products with a C<sub>60</sub>-fused tetrahydrofuran ring skeleton and an acetal moiety.<sup>5</sup> The research groups of Tajima<sup>3a</sup> and Gan<sup>3b</sup> realized the synthesis of C<sub>60</sub>-fused 1,3-dioxolane derivatives from fullerene epoxides through the reactions with aldehydes or acetone in the presence of a Lewis acid. Two orthoester-type 1,3-dioxolanofullerenes were also reported.<sup>4</sup> Among the reported C<sub>60</sub>-fused 1,3-dioxolane derivatives, only four were prepared directly from C<sub>60</sub>.<sup>2,4</sup> Therefore, it is still demanding to develop new protocol to obtain C<sub>60</sub>-fused 1,3-dioxolane derivatives directly from C<sub>60</sub> in a straightforward and efficient way with a broad substrate scope.

Recently, our group has been interested in reactions of C<sub>60</sub> mediated by metal salts such as Mn(OAc)<sub>3</sub>,<sup>6,7</sup> Cu(OAc)<sub>2</sub>,<sup>7c</sup> Pb(OAc)<sub>4</sub>,<sup>7h</sup> or Pd(OAc)<sub>2</sub><sup>8</sup> to prepare a series

of novel fullerene derivatives. We also reported the synthesis of rare fullerooxazoles by the  $\text{Fe}(\text{ClO}_4)_3$ -mediated reaction of  $\text{C}_{60}$  with a variety of nitriles,<sup>9</sup> which is the first example for the direct reaction of  $\text{C}_{60}$  with the unsaturated carbon–nitrogen triple bond moiety of nitriles in the presence of water. In continuation of our interest in  $\text{Fe}(\text{ClO}_4)_3$ -mediated reactions of  $\text{C}_{60}$ ,<sup>9</sup> herein we describe the  $\text{Fe}(\text{ClO}_4)_3$ -mediated one-step reaction of  $\text{C}_{60}$  with aldehydes or ketones to afford a variety of scarce  $\text{C}_{60}$ -fused 1,3-dioxolane derivatives.

In our previous study, we found that the direct dissolution<sup>10</sup> of  $\text{Fe}(\text{ClO}_4)_3$  by nitriles played a crucial role for the successful synthesis of fullerooxazoles.<sup>9</sup> Similarly, we explored the  $\text{Fe}(\text{ClO}_4)_3$ -promoted reaction of  $\text{C}_{60}$  with various aldehydes by adopting the direct dissolution method, i.e.,  $\text{Fe}(\text{ClO}_4)_3$  was first dissolved in a chosen aldehyde, and then the dichlorobenzene (ODCB) solution of  $\text{C}_{60}$  was added. Much to our satisfaction, we found that the  $\text{Fe}(\text{ClO}_4)_3$ -mediated reaction of  $\text{C}_{60}$  with aldehydes **1a–k**, that is, benzaldehyde (**1a**), *p*-tolualdehyde (**1b**), 4-methoxybenzaldehyde (**1c**), 3,4-dimethylbenzaldehyde (**1d**), 4-chlorobenzaldehyde (**1e**), 2-chlorobenzaldehyde (**1f**), *p*-phthalaldehyde (**1g**), 4-nitrobenzaldehyde (**1h**), 4-cyanobenzaldehyde (**1i**), cinnamaldehyde (**1j**), and propionaldehyde (**1k**), afforded  $\text{C}_{60}$ -fused 1,3-dioxolane derivatives **2a–k**.

Initially, the  $\text{Fe}(\text{ClO}_4)_3$ -promoted reaction of  $\text{C}_{60}$  with **1a** was chosen to screen the reaction conditions. The details are listed in Table S1 in the Supporting Information. Screening experiments indicated that the best molar ratio of  $\text{C}_{60}:\text{Fe}(\text{ClO}_4)_3:\text{xH}_2\text{O}:\mathbf{1a}$  was 1:2:5, and the reaction temperature was 80 °C. These optimized reaction conditions could be extended to other aldehydes except that higher temperature was required for the melting of **1g–i** and subsequent dissolution of  $\text{Fe}(\text{ClO}_4)_3$ , and more propionaldehyde was demanded due to its lower boiling point and thus easier evaporation. The reaction conditions and yields for the  $\text{Fe}(\text{ClO}_4)_3$ -mediated reaction of  $\text{C}_{60}$  with aldehydes **1a–k** are summarized in Table 1. The progress of the reactions should be carefully monitored by TLC to prevent overreaction.

As can be seen from Table 1, aromatic aldehydes bearing either electron-donating or electron-withdrawing groups (**1a–i**), cinnamaldehyde (**1j**), as well as aliphatic aldehyde (**1k**) could be successfully employed to prepare the  $\text{C}_{60}$ -fused 1,3-dioxolane derivatives in 14–38% yields (30–91% based on consumed  $\text{C}_{60}$ ). For the synthesis of compound **2a**, the

<sup>a</sup> All reactions were performed under protection of nitrogen with a molar ratio of  $\text{C}_{60}:\text{Fe}(\text{ClO}_4)_3:\text{xH}_2\text{O}:\mathbf{1} = 1:2:5$  unless otherwise indicated. <sup>b</sup> Molar ratio of  $\text{C}_{60}:\text{Fe}(\text{ClO}_4)_3:\text{xH}_2\text{O}:\mathbf{1k} = 1:2:50$ . <sup>c</sup> Isolated yield; the number in parentheses was based on consumed  $\text{C}_{60}$ .

current  $\text{Fe}(\text{ClO}_4)_3$ -mediated reaction of  $\text{C}_{60}$  with benzaldehyde is preferable to the reaction of  $\text{C}_{60}$  with  $\text{PhCH}_2\text{ONa}$ - $\text{PhCH}_2\text{OH}$ , which generated product **2a** in 15% yield (68% based on consumed  $\text{C}_{60}$ ).<sup>2b</sup> The cyano group is known to react with  $\text{C}_{60}$  in the presence of  $\text{Fe}(\text{ClO}_4)_3$ .<sup>9</sup> Nevertheless, no corresponding fullerooxazole could be identified from the  $\text{Fe}(\text{ClO}_4)_3$ -mediated reaction of  $\text{C}_{60}$  with substrate **1i**, demonstrating the superior reactivity of the aldehyde group over the cyano group.

(10) The term “melting” in ref 9 should be better expressed as “dissolution”.

Product **2a**<sup>2b,3a</sup> is a known compound, and its identity was confirmed by comparison of its spectral data with those reported in the literature. New compounds **2b–k** were unambiguously characterized by their HRMS, <sup>1</sup>H NMR, <sup>13</sup>C NMR, FT-IR, and UV–vis spectra. In the <sup>1</sup>H NMR spectra of compounds **2b–k**, the methine proton on the heterocycle ring appeared in very downfield region (6.3–7.6 ppm). In their <sup>13</sup>C NMR spectra, the observation of no more than 30 lines for the sp<sup>2</sup>-carbons of the C<sub>60</sub> skeleton was consistent with their C<sub>s</sub> molecular symmetry, and the signals for the sp<sup>3</sup>-carbons of the acetal and fullerene moiety were located at 99.2–104.1 and 93.5–94.6 ppm, close to those of reported C<sub>60</sub>-fused 1,3-dioxolane derivatives in the previous literature.<sup>2,3</sup>

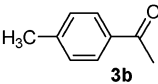

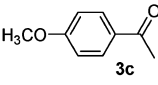

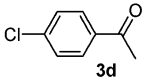

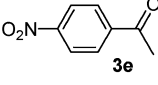

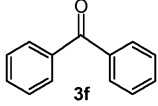

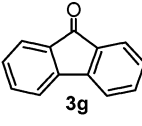

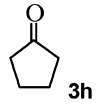

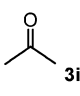

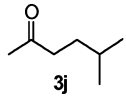

To expand the scope of the reaction, the substrates were extended from aldehydes to ketones. Acetophenone (**3a**), 4-methylacetophenone (**3b**), 4-methoxyacetophenone (**3c**), 4-chloroacetophenone (**3d**), 4-nitroacetophenone (**3e**), benzophenone (**3f**), 9-fluorenone (**3g**), cyclopentanone (**3h**), acetone (**3i**), and 5-methyl-2-hexanone (**3j**) were chosen to react with C<sub>60</sub> in the presence of Fe(ClO<sub>4</sub>)<sub>3</sub> by the direct dissolution method, and were found to generate C<sub>60</sub>-fused 1,3-dioxolane derivatives **4a–j**.

The reaction conditions and yields for the Fe(ClO<sub>4</sub>)<sub>3</sub>-mediated reaction of C<sub>60</sub> with ketones **3a–j** are summarized in Table 2.

As can be seen from Table 2, both aromatic ketones (**3a–g**) and aliphatic ketones (**3h–j**) could be successfully utilized to prepare the C<sub>60</sub>-fused 1,3-dioxolane derivatives **4a–j** in 9–29% yields (24–68% based on consumed C<sub>60</sub>). The acyclic aromatic ketones (**3a–f**) gave reasonably good isolated yields except 4-nitroacetophenone (**3e**), which afforded some byproducts. 9-Fluorenone also generated low yield probably due to the steric interactions from the two hydrogens at the C<sub>1</sub> and C<sub>8</sub> positions in the rigid ring system. Aliphatic ketones (**3h–j**) generally afforded good product yields. The isolated yield of C<sub>60</sub>-fused 1,3-dioxolane derivative **4i** by our current protocol (18%, 44% based on consumed C<sub>60</sub>) was much higher than that by the previously reported procedure (5%, 7% based on consumed C<sub>60</sub>).<sup>2a</sup>

The structures of C<sub>60</sub>-fused dioxolanes **4a–j** were fully established by HRMS, <sup>1</sup>H NMR, <sup>13</sup>C NMR, FT-IR, and UV–vis spectra. In their <sup>13</sup>C NMR spectra, dioxolanes **4a–e** together with **4j** showed similar spectral patterns with those from aldehydes **1a–k**. No more than 29 peaks including some overlapped ones due to the 58 sp<sup>2</sup>-carbons of the fullerene moiety were observed in the range of 137.3–149.4 ppm, consistent with the C<sub>s</sub> symmetry of the molecular structures, and the peaks for the two sp<sup>3</sup>-carbons of the C<sub>60</sub> cage and ketal carbon appeared at 94.4–95.1 and 110.6–113.8 ppm. However, the remaining dioxolanes **4f–i** exhibited different spectral patterns with the above-mentioned dioxolanes. The observation of only 14–16 lines for the sp<sup>2</sup>-carbons of the C<sub>60</sub> skeleton agreed well with the C<sub>2v</sub> molecular symmetry, and the two sp<sup>3</sup>-carbons and ketal carbon were located at 93.5–95.6 and 111.7–120.7 ppm. Interestingly, the chemical shifts for the ketal carbons (110.6–120.7 ppm) in the dioxolanes **4a–j** were shifted

**Table 2.** Reaction Conditions and Yields for the Reaction of C<sub>60</sub> with Ketones **3a–j** in the Presence of Fe(ClO<sub>4</sub>)<sub>3</sub>·xH<sub>2</sub>O<sup>a</sup>

downfield about 11–17 ppm from those of the acetal carbons in the dioxolanes **2b–k** (99.2–104.1 ppm). In addition, the identity of **4i** was further confirmed by comparison of its spectral data with those reported previously.<sup>2a</sup>

We previously reported that the reaction of methyl ketones with C<sub>60</sub> promoted by Mn(OAc)<sub>3</sub>/Cu(OAc)<sub>2</sub> gave C<sub>60</sub>-fused dihydrofurans and/or methanofullerenes.<sup>7c</sup> However, no evidence for the formation of C<sub>60</sub>-fused dihydrofuran and/

**Scheme 1.** Proposed Reaction Mechanism for the Formation of C<sub>60</sub>-Fused 1,3-Dioxolanes

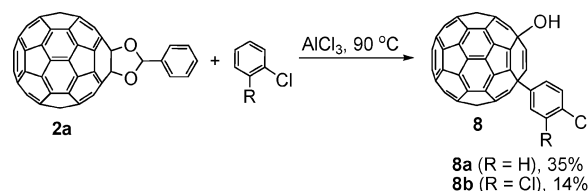

or methanofullerene could be obtained from the current  $\text{Fe}(\text{ClO}_4)_3$ -mediated reaction of  $\text{C}_{60}$  with methyl ketones. Obviously, different reaction mechanisms are operating for the reaction of  $\text{C}_{60}$  with methyl ketones mediated by  $\text{Fe}(\text{ClO}_4)_3$  and  $\text{Mn}(\text{OAc})_3/\text{Cu}(\text{OAc})_2$ . On the basis of the previously suggested mechanism for the reaction of  $\text{C}_{60}$  with various nitriles in the presence of  $\text{Fe}(\text{ClO}_4)_3$  to afford the fullereroxazoles,<sup>9</sup> we propose a possible mechanism for the formation of  $\text{C}_{60}$ -fused 1,3-dioxolanes **2/4** from the  $\text{Fe}(\text{ClO}_4)_3$ -mediated reaction of  $\text{C}_{60}$  with aldehydes/ketones, as shown in Scheme 1. A chosen aldehyde or ketone reacts with the hydrated  $\text{H}_2\text{O}$  in  $\text{Fe}(\text{ClO}_4)_3 \cdot x\text{H}_2\text{O}$  to produce  $\text{Fe}(\text{III})$ -complex **5** accompanied by the loss of  $\text{HClO}_4$ . The observed reddening of the mixtures of aldehydes/ketones and  $\text{Fe}(\text{ClO}_4)_3 \cdot x\text{H}_2\text{O}$  hints the formation of complexes between  $\text{Fe}(\text{ClO}_4)_3 \cdot x\text{H}_2\text{O}$  and aldehydes/ketones.<sup>11</sup> Homolytical addition of **5** to  $\text{C}_{60}$  generates fullerene radical **6** with an elimination of  $\text{Fe}(\text{ClO}_4)_2 \cdot (x-1)\text{H}_2\text{O}$ , and then coordination with another molecule of  $\text{Fe}(\text{ClO}_4)_3 \cdot x\text{H}_2\text{O}$  to form  $\text{Fe}(\text{III})$ -complex **7**, which undergoes intramolecular cyclization with the loss of a  $\text{Fe}(\text{II})$  species to afford  $\text{C}_{60}$ -fused 1,3-dioxolanes **2/4**.

The  $\text{C}_{60}$ -fused 1,3-dioxolane derivatives can be valuable precursors for further functionalization. Preliminary results showed that treatment of  $\text{C}_{60}$ -fused 1,3-dioxolane derivative **2a** with  $\text{AlCl}_3$  in chlorobenzene and 1,2-dichlorobenzene at 90 °C afforded 4-chlorophenyl- and 3,4-dichlorophenyl-substituted fullereneols in 35% and 14% yield, respectively

(11) Citterio, A.; Sebastiano, R.; Carvayal, M. C. *J. Org. Chem.* **1991**, 56, 5335.

(12) Tajima, Y.; Hara, T.; Honma, T.; Matsumoto, S.; Takeuchi, K. *Org. Lett.* **2006**, 8, 3203.

**Scheme 2.** Reaction of C<sub>60</sub>-Fused Dioxolane **2a** with Chlorobenzene and 1,2-Dichlorobenzene in the Presence of Aluminum Chloride

(Scheme 2). Tajima et al.<sup>12</sup> reported the  $\text{BF}_3 \cdot \text{Et}_2\text{O}$ -assisted nucleophilic substitution of  $\text{C}_{60}\text{O}$ . They found that the progress of the reaction depended considerably on the nucleophilicity of the aromatic compound, and chlorobenzene failed to react with  $\text{C}_{60}\text{O}$ . Even though the reaction mechanism for the formation of fullereneols **8** is not quite clear now, the reaction should occur via a carbocationic intermediate generated with the assistance of  $\text{AlCl}_3$ . It is intriguing that electron-deficient chlorobenzene and 1,2-dichlorobenzene could react in our case.

In summary, the synthesis of scarce  $\text{C}_{60}$ -fused 1,3-dioxolanes has been achieved by the  $\text{Fe}(\text{ClO}_4)_3$ -promoted reaction of  $\text{C}_{60}$  with aldehydes or ketones. It is noteworthy that functional groups such as Cl, CHO,  $\text{NO}_2$ , and CN could be tolerated under our reaction conditions and can be further transformed to other moieties. The current one-step approach to the preparation of  $\text{C}_{60}$ -fused 1,3-dioxolanes from cheap and easily accessible aldehydes/ketones and  $\text{Fe}(\text{ClO}_4)_3$  was obviously more straightforward and practical than the previous protocols.<sup>2,3a</sup> The direct dissolution of aldehydes/ketones and  $\text{Fe}(\text{ClO}_4)_3$  proved to be crucial for the efficient synthesis of  $\text{C}_{60}$ -fused 1,3-dioxolanes. A plausible reaction mechanism for the formation of  $\text{C}_{60}$ -fused 1,3-dioxolanes is suggested.
