Lithiation by MeLi of three families of branched polysilanes $(Me_3Si)_3Si-X\{(1)\ X=SiMe_2H,$ t-BuMe₂Si, SiMe₂SiMe₃, t-BuSiMe₂SiMe₂; (2) X = SiMe(SiMe₃)₂, Si(SiMe₃)₃, SiMe₂Si(SiMe₃)₃, $SiMeHSi(SiMe_3)_3$; (3) $X = Si(SiMe_3)_2Cl$, $Si[Si(SiMe_3)_3]MeCl$, $Si[Si(SiMe_3)_3]HCl$ } yields, depending on X, one of the following: (a) novel branched polysilyllithium compounds; (b) the known (Me₃Si)₃SiLi; (c) various mixtures. The cleavage of family 1 can be understood in terms of steric effects, i.e., assuming that MeLi attacks preferentially the sterically less hindered Si atom leading to the formation of new polysilyllithium compounds, e.g., t-BuMe2-Si(Me₃Si)₂SiLi·3THF and t-BuMe₂SiSiMe₂(Me₃Si)₂SiLi·3THF, which were isolated in a crystalline form. The X-ray structure of the former is presented. In contrast to 1 the lithiation of the branched polysilanes 2 leads exclusively (mostly with (Me₃Si)₃SiSiMe-(SiMe₃)₂) to the known (Me₃Si)₃SiLi. Lithiation of 3 leads to a number of novel polysilyllithium compounds. We tentatively propose that the lithiation of 3 proceeds by a two step reaction in which a disilene is formed as an intermediate, and this is followed by fast addition of a second molecule of MeLi to produce the final silyllithium product.

Introduction

Many of the recent achievements in silicon chemistry are connected to the branched "hypersilyl" anion, (Me3-Si)₃Si⁻,¹ first prepared in situ by Gilman and Smith² and later isolated as a stable DME^{3a} or THF^{3b} complex of its lithium salt, e.g., (Me₃Si)₃SiLi·3THF. For example, (Me₃Si)₃SiLi was used in the synthesis of the first stable silene (Me₃Si)₂Si=CR(OSiMe₃),⁴ iminoborane (Me₃Si)₃SiB=NCR₃,⁵ and formylsilane (Me₃Si)₃SiC-(=O)H.6 Furthermore, the large steric requirements of compounds containing the (Me₃Si)₃Si group and their good solubility in organic solvents make this "hypersilyl" substituent a popular ligand in main-group⁷ and in transition metal-chemistry.8 Recently there was also considerable interest in the electronic9a and steric9b,10 properties of the "hypersilyl" group. In view of the

above and the recent interest in polysilane dendrimers¹¹ we have embarked on a program to prepare more highly branched polysilanes, which can be used to stabilize a variety of organosilicon reactive intermediates, e.g. silenes, disilenes, silylenes, and silicenium ions. We report here a new synthetic method that allows us to prepare a variety of novel branched polysilane anions.

Our strategy is based on the facile cleavage of branched polysilanes by alkyl lithium reagents to give silyl anions (e.g., reaction 1 for $X = Me_3Si$, Me, t-Bu, Ph).12

$$(Me_3Si)_3SiX + MeLi \longrightarrow X(Me_3Si)_2SiLi + Me_4Si$$
 (1)

Results and Discussion

We have studied the outcome of reaction 1 for three families of branched polysilanes of the general type (Me₃Si)₃SiX, shown in Chart 1, where X was varied as follows: In family 1, X has either one or two silicon atoms. In 2, X is a branched polysilane fragment

containing up to six silicon atoms. In **3**, X is a branched *chloro*-substituted polysilane with up to 5 silicon atoms.

The required $(Me_3Si)_3SiX$ polysilanes (1-3) were prepared by coupling reactions of $(Me_3Si)_3SiLi\cdot 3THF$ with the appropriate chlorosilanes. For example, 1b, d were prepared by the coupling of $(Me_3Si)_3SiLi\cdot 3THF$ in toluene at -78 °C with t-BuSiMe₂Cl or t-BuMe₂SiSiMe₂-Cl, respectively. $[(Me_3Si)_3Si]_2SiHCl$, 3c, the first known silane with two "hypersilyl" substituents bonded to the same silicon atom, was prepared in 68% yield by the very slow addition at -78 °C of $HSiCl_3$ to a toluene solution of a 2-fold molar excess of $(Me_3Si)_3SiLi\cdot 3THF$. 2c, d and 3d were synthesized from 3c by standard methylation and chlorination reactions. The details of these syntheses are given in the Experimental Section.

Lithiation with MeLi of polysilanes belonging to family **1** gave the results shown in Table 1. The relative yields of the silyllithium products were determined by GC/MS analysis of the product mixtures obtained by quenching of the reaction mixtures with the following: (a) water, leading to the hydrolysis products HSi-(SiMe₃)₂SiR₃ and HSi(SiMe₃)₃; (b) ClCH₂OCH₃, leading to the corresponding methyl ethers CH₃OCH₂Si(SiMe₃)₂-SiR₃ and CH₃OCH₂Si(SiMe₃)₃.

The results in Table 1 indicate that the polysilanes **1** are cleaved by two major pathways (eq 2). The desired

novel silyllithium reagents are formed via path A in eq 2, while cleavage of the Si-X bond (path B) leads to the undesired formation of (Me₃Si)₃SiLi (and of the corresponding Me₃SiR silane).

The cleavage of polysilanes of family 1 can be understood in terms of steric effects, i.e., assuming that MeLi attacks preferentially at the sterically less hindered Si atom. Thus, with 1a when R = H (eq 2) attack occurs exclusively at the less hindered SiHMe₂ group (path B) and (Me₃Si)₃SiLi is the only silyllithium product which is observed. With **1b**, where R is the larger *t*-Bu group, attack occurs exclusively at the terminal Me₃Si group and cleavage occurs along path A to give the novel polysilyl lithium reagent 4. Path A predominates the cleavage reaction also with **1d** where a *t*-Bu group is in the β -position, i.e. **1**, with R = t-BuMe₂Si, leading to the novel 5 (Table 1). When the t-Bu group in 1b is substituted by the smaller SiMe₃ group¹⁰ (**1c**), path B competes to ca. 30%. The new silyllithium reagents obtained via reaction 2, 4 and 5, were both isolated in excellent yields.

Attempts to use the same strategy to produce more highly branched polysilyl anions were disappointing. In contrast to 1 the lithiation of the branched polysilanes 2 leads exclusively (or mostly with 2a) to cleavage along the undesired path B (Table 1). Steric effects alone cannot account for the observed cleavage patterns of 2. Thus, although the t-Bu and the (Me₃Si)₃Si groups have similar steric sizes, 10 cleavage of (Me₃Si)₃SiSiMe₂Si-(SiMe₃)₃ (2d) occurs exclusively along path B (yielding (Me₃Si)₃SiLi), while the cleavage of t-BuMe₂SiSi(SiMe₃)₃ (**1b**) occurs exclusevely along path A (eq 2). Apparently, the undesired cleavage of the internal Si-Si bond (path B) is facilitated by the branched polysilyl substituent present in 2b-d, indicating that the electronic effect of these branched polysilyl groups is more important than their steric bulk in dictating the cleavage of 2.

The cleavage reaction takes an entirely different course with the highly branched *chloro*-substituted polysilanes of type **3** (Table 2). Lithiation of **3** with 2 mol of MeLi (PhLi was also used in the case of **3c**) leads to the formation (in 50-60% yield) of the corresponding novel branched silyl anions, previously unknown, as

 a See eq 3. b Identified as the corresponding $R_1R_2MeSiSi(SiMe_3)_2H$ or $R_1R_2MeSiSi(SiMe_3)_2CH_2OCH_3$ after quenching with water or with CH_3OCH_2Cl , respectively. c Similar results were obtained in the reaction with phenyllithium.

Chart 2 ŞiMe₃ Me₃SiMe₂Si ·Ši Li SiMe₃ 6a 6b SiMe₃ Me SiMe₃ Me Me₃Şi SiMe₃ Me_3Si Me SiMe 6c

shown in eq 3. The other observed product is MeR₁R₂-

SiSi(SiMe₃)₃, resulting from substitution of chlorine by a methyl group (from MeLi). Using this reaction, four new silyllithium reagents, $\bf 6$ (Chart 2), were prepared and identified by their hydrolysis products and the ethers produced in their reaction with CH₃OCH₂Cl (i.e., MeR₁R₂SiSi(SiMe₃)₂CH₂OCH₃; see Experimental Section).

We first assumed that reaction 3 proceeds *via* the twostep mechanism shown in eq 4 involving the following: (a) substitution of Cl by Me; (b) lithiation.

However, the significant differences in the cleavage selectivity between polysilanes of type **3** and of type **2** shows that this cannot be the case. For example, according to the above mechanism cleavage of **3c** or **3d** should have produced (Me₃Si)₃SiLi, the cleavage product of **2c** or **2d** (Table 1), in contrast to observation (Table 2). The cleavage reactions of compounds of families **3** and **2** are contrasted in Scheme 1.

We tentatively propose that the cleavage of **3** proceeds by an elimination—addition mechanism (either con-

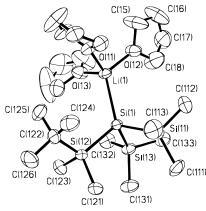

Figure 1. Molecular structure of **4** (one of the two independent molecules shown). Hydrogen atoms have been omitted for clarity. Probability ellipsoids at the 50% level are shown.

certed or stepwise) *via a disilene intermediate*, as shown schematically in eq 5. Studies designed to support this interesting mechanism are in progress.

$$Me_{3}Si \xrightarrow{R^{1}} CI \xrightarrow{-Me_{4}Si}$$

$$Me_{3}Si \xrightarrow{R^{2}} R^{2} \xrightarrow{-LiCI}$$

$$Me_{3}Si \xrightarrow{R^{2}} Si \xrightarrow{R^{2}} MeLi \xrightarrow{R^{1}} SiMe_{3}$$

$$Me_{3}Si \xrightarrow{R^{2}} R^{2} \xrightarrow{MeLi} Me \xrightarrow{Si} SiLi \qquad (5)$$

$$R^{2}SiMe_{3}$$

The reaction of branched chloropolysilanes with MeLi (reaction 3) opens new possibilities to synthesize a variety of novel highly branched polysilyl anions. Additional experimental studies as well as *ab initio* calculations are in progress in order to provide a better understanding of the cleavage mechanisms of branched polysilanes.

Structural Data for 4. 4 is a crystalline compound, and its X-ray structure could be determinated.¹³ The unit cell (see Supporting Information) contains four molecules, but **4** is essentially monomeric in the crystaline form, as evidenced by the fact that the shortest intramolecular atomic distances within the unit cell are larger than 4.0 Å. Two of the four molecules are independent, but as they have essentially identical

⁽¹³⁾ Crystallographic data for 4: MW = 342.00; crystal system monoclinic, space group $P2_1$; a=11.062(2) Å, b=16.3331(3) Å, c=18.906(4) Å; $\beta=99.49(3)$; V=3370.8(11) ų; $d_{\rm calcd}=1.011$ g cm $^{-3}$ for Z=4 at 293(2) K; R=0.0623, $R_{\rm w}=0.1516$. Details of data collection and refinement are given in the Supporting Information.

geometric parameters, we discuss below only the geometry of one of these molecules.

An ORTEP picture of the X-ray structure of 4^{13} is presented in Figure 1, and the most important bond distance and bond angles are given in Table 3. The molecular structure of 4 resembles closely that of the analogous (Me₃Si)₃SiLi·3THF.^{14a} The Si-Li distance in 4 of 2.680 Å is quite similar to that in (Me₃Si)₃SiLi·3THF (2.669 Å). The Si-Si-Si angles at the negatively charged silicon are quite acute (102°) as in other known silyllithium compounds.3a,14 The Si-Si bond lengths have a narrow range, 2.338-2.353 Å, longer by 0.01 Å than in (Me₃Si)₃SiLi·3THF.^{14a} The only significant structural consequence of replacing a methyl in the (Me₃Si)₃Si group by the bulkier t-Bu group is the significantly elongated β -Si(12)–C(122) bond (1.92 Å) vs ca. 1.87–1.89 Å for the two other β -Si–Me bonds (i.e., Si(12)–C(121) and Si(12)–C(123)) or the α -Si–Me bonds.

Experimental Section

Standard Schlenk techniques were used for all syntheses and all sample manipulations. NMR spectra were recorded at room temperature in $CDCl_3$ or C_6D_6 solutions using a Bruker EM-200 or Bruker-400 instrument. Mass spectroscopy (MS) data were obtained with a Finnigan MAT TSQ 45 triple-stage quadrupole mass spectrometer. Elemental analyses were performed by the Microanalytical Laboratory of the University of Essen (Essen, Germany).

Preparation of 1 and 3a,b. The corresponding chlorosilane [HMe₂SiCl, *t*-BuMe₂SiCl, Me₃SiMe₂SiCl, *t*-BuMe₂SiMe₂-SiCl] or dichlorodisilanes [Cl₂MeSiMe₂Si, Cl₂Si(SiMe₃)₂] (15 mmol) in 50 mL of toluene was added to a solution of 10 mmol of (Me₃Si)₃SiLi in 40 mL of toluene cooled to -78 °C. All

operations were carried out under vacuum using Schlenk techniques. The reaction mixture was stirred at room temperature for 10 h. The pure products were isolated after filtration of the reaction mixture and evaporation of the solvent, in yields >95%.

(Me₃Si)₃SiMe₂SiSiMe₂Bu-t (1d). ¹H NMR (CDCl₃): δ 0.08 (6H, s, Me₂Si), 0.20 (27H, s, Me₃Si), 0.32 (6H, s, SiSiMe₂Si), 0.92 (9H, s, t-Bu). ²⁹Si NMR (C₆D₆): δ -128.0 (quaternary silicon), -36.4 (SiSiMe₂Si), -9.5 (Me₃Si), -6.3 (t-BuSi). MS-(EI): m/e 420 (M⁺), 405 (M⁺ - Me), 363 (M⁺ - t-Bu). Anal. Calcd for C₁₇H₃₄Si₅: C, 44.37; H, 11.71. Found: C, 43.88; H, 11.96.

(Me₃Si)₃SiSiClMeSiMe₃ (3a). ¹H NMR (CDCl₃): δ 0.19 (9H, s, Me₃SiSiCl), 0.24 (27H, s, (Me₃Si)₃Si), 0.66 (6H, s, Me₂-SiCl). ²⁹Si NMR (C₆D₆): δ -124.0 ((Me₃Si)₃Si), -66.5 (SiCl), -13.1 (ClSiSi), -9.5 ((Me₃Si)₃Si). MS(EI): m/e 383 (M⁺ - Me), 363 (M⁺ - Cl), 325 (M⁺ - Me₃Si). Anal. Calcd for C₁₁ClH₃₄-Si₅: C, 43.06; H, 11.17. Found: C, 43.58; H, 10.90.

(Me₃Si)₃SiSiCl(SiMe₃)₂ (3b) was purified by column chromotography on silica gel with hexane as eluent. ¹H NMR (CDCl₃): δ 0.19 (18H, s, Si(SiMe₃)₂), 0.27 (27H, s, Si(SiMe₃)₃). ²⁹Si NMR (C₆D₆): δ -135.5 (SiSiSi), -121.2 (SiCl), -10.0 ((Me₃Si)₃Si-), -9.0 ((SiMe₃)₂SiCl). MS(EI): m/e 441 (M⁺ - Me), 421 (M⁺ - Cl), 363 (M⁺ - Me₃Si). Anal. Calcd for C₁₅-ClH₄₅Si₇: C, 39.38; H, 9.91. Found: C, 39.87; H, 10.50.

(Me₃Si)₃SiSiMe(SiMe₃)₂ (2a). An equimolar amount of MeLi in ether was added to a solution of 3b in THF at $-30\,^{\circ}$ C and then stirred for 10 h at room temperature. After aqueous workup the product was isolated by column chromatography on silica gel with hexane as eluent. 1H NMR (CDCl₃): δ 0.17 (18H, s, (Me₃Si)₂Si), 0.22 (27H, s, (Me₃Si)₃Si). 29 Si NMR (C₆D₆): δ -129.2 (quaternary silicon), -78.9 ((Me₃Si)₂Si), -11.0 ((Me₃Si)₂Si), -9.0 ((Me₃Si)₃Si). MS(EI): $\emph{m/e}$ 436 (M⁺), 421 (M⁺ - Me), 363 (M⁺ - Me₃Si), 348 (M⁺ - MeSiMe₃). Anal. Calcd for C₁₆H₄₈Si₆: C, 43.96; H, 11.07. Found: C, 43.75; H, 10.64.

(Me₃Si)₃SiSi(SiMe₃)₃ (2b) was prepared according to the following: Gilman, H.; Harrell, R. L., Jr. *J. Organomet. Chem.* **1967**, *9*, 67.

[(Me₃Si)₃Si]₂SiHCl (3c). A 5 mmol amount of HSiCl₃ in 150 mL of hexane cooled to -30 °C was very slowly added (by vacuum transfer) to a solution of 10 mmol of (Me₃Si)₃SiLi-3THF in 100 mL of toluene, cooled to -78 °C. The reaction mixture was stirred overnight at -78 °C and then for 12 h at room temperature. After evaporation of the solvent and sublimation of the solid residue (110 °C/1 mmHg), 1.73 g (63%) of 3c was obtained. ¹H NMR (CDCl₃): δ 0.26 (54H, s, Me₃Si), 5.40 (1H, s, SiH). MS(EI): m/e 557 (M⁺ – H). Anal. Calcd for C₁₈ClH₅₅Si₉: C, 38.62; H, 9.90. Found: C, 39.16; H, 10.14.

[(Me₃Si)₃Si]₂SiHMe (2c). The equivalent amount of MeLi in ether was added at room temperature to an ether solution of **3c**, and it was stirred for 10 h. The product was isolated by column chromatography on silica gel with hexane as eluent. ¹H NMR (CDCl₃): δ 0.23 (54H, s, Me₃Si), 0.39, 0.42 (3H, d, MeSi), 3.92 (1H, m, HSi). MS(EI): m/e 523 (M⁺ – Me), 464

 $(M^+ - HSiMe_3)$, 450 $(M^+ - MeSiMe_3)$. Anal. Calcd for $C_{19}H_{58}$ -Si₉; C, 42.31; H, 10.84. Found: C, 41.95; H, 10.35.

[(Me₃Si)₃Si]₂SiHClMe (3d). A mixture of 0.7 g (1.3 mmol) of 2c and 0.3 g (1.5 mmol) of PCl₅ in 20 mL of CCl₄ was stirred at 80 °C for 10 h. After solvent evaporation and sublimation (110 °C/1 mmHg), 0.5 g (0.9 mmol, 70%) of 3d was isolated. ^1H NMR (CDCl₃): δ 0.27 (54H, s, Me₃Si), 0.89 (3H, s, MeSi). MS(EI): m/e 557 (M⁺ - Me), 537 (M⁺ - Cl), 499 (M⁺ - Me₃Si). Anal. Calcd for C₁₉ClH₅₇Si₉: C, 39.77; H, 10.01. Found: C, 38.98; H, 10.40.

[(Me₃Si)₃Si]₂SiMe₂ (2d). An equimolar amount of MeLi in ether was added to a solution of 3d in THF at -30 °C and then stirred for 10 h at room temperature. After aqueous workup the product was isolated by column chromatography on silica gel with hexane as eluent. ¹H NMR (CDCl₃): δ 0.23 (54H, s, Me₃Si), 0.30 (6H, s, Me₂Si). MS(EI): m/e 537 (M⁺ – Me), 464 (M⁺ – MeSiMe₃), 305 (M⁺ – Si (SiMe₃)₃). Anal. Calcd for C₂₀H₆₀Si₉: C, 42.40; H, 10.93. Found: C, 43.11; H, 10.81.

t-BuMe₂Si(SiMe₃)₂SiLi·3THF (4) and *t*-BuMe₂SiSiMe₂-(Me₃Si)₂SiLi·3THF (5) were prepared by lithiation of silanes 1b,d, respectively. Crystallization from hexane at room temperature resulted in the formation of colorless crystals.

t-BuMe₂Si(SiMe₃)₂SiLi·3THF (4). ¹H NMR (C_6D_6): δ 0.45 (6H, s, Me₂Si), 1.05 (18H, s, (Me₃Si)₂), 1.19 (9H, s, *t*-Bu). ¹³C NMR (C_6D_6): δ 1.9 (Me₂Si), 7.6 (Me₃Si), 18.7 (Me₃C–), 25.6 (Me₃C–). ²⁹Si NMR (C_6D_6): δ –0.192.8 (*t*-BuSi S_6 Si), -5.2 (Me₃Si), 9.4 (*t*-BuSi).

t-BuMe₂SiSiMe₂(Me₃Si)₂SiLi·3THF (5). ¹H NMR (C₆D₆): δ 0.21 (6H, s, SiSiMe₂Si), 0.51 (18H, s, Si(SiMe₃)₂), 0.68 (6H, s, *t*-BuSi*Me*₂), 1.15 (9H, s, *t*-Bu). ¹³C NMR (C₆D₆): δ -7.34 (*t*-BuSi*Me*₂), 3.31 (SiSi*Me*₂Si), 7.39 (SiMe₃), 19.21 (Me₃*C*), 25.37 (*Me*₃C). ²⁹Si NMR (C₆D₆): δ -178.1 (SiLi), -36.4 (SiSiSi), -9.5 (Me₃Si), -6.3 (*t*-BuSi).

Lithiation of 3 was carried out (using Schlenk techniques) by slow addition (2-3 h) of 2 equiv of MeLi in ether to a THF solution of **3** at -30 °C. The yellow-orange reaction mixture was kept at 0 °C for 10 h. An excess of ClCH₂OCH₃ was added to the reaction mixture, and the corresponding ethers CH₃-OCH₂Si(SiMe₃)₂X were isolated by column chromatography on silica gel with hexane as eluent.

CH₃OCH₂Si(SiMe₃)₂SiMe₂SiMe₃ (obtained from **6a**). ¹H NMR (CDCl₃): δ 0.14 (9H, s, Me₃Si), 0.16 (18H, s, (SiMe₃)₂Si), 0.34 (6H, s, Me₂Si), 3.23 (3H, s, O-CH₃), 3.41 (2H, s, -CH₂O-). MS (EI): m/e 335 (M⁺ - Me), 277 (M⁺ - Me₃Si), 247 (M⁺ - Me₃SiOMe).

CH₃OCH₂Si(SiMe₃)₂Si(SiMe₃)₂Me (obtained from **6b**). ¹H NMR (CDCl₃): δ 0.14 (18H, s, $(Me_3Si)_2Si-CH_2OCH_3)$, 0.16 (18H, s, $(Me_3Si)_2SiMe)$, 0.17 (3H, s, MeSi), 3.20 (3H, s, $-OCH_3$), 3.41 (2H, s, SiCH₂O). HRMS: calcd for $C_{15}H_{44}OSi_6$ (M⁺ - Me) m/e 393.1794, found 393.1796. MS (EI): 335 (M⁺ - Me₃Si), 304 (M⁺ - Me₃SiOMe).

CH₃OCH₂Si(SiMe₃)₂SiHMeSi(SiMe₃)₃ (obtained from **6c**).
¹H NMR (CDCl₃): δ 0.17, 0.19 (18H, d, (Me₃Si)₂Si), 0.21 (27H, s, (Me₃Si)₃Si), 0.28, 0.31 (3H, d, MeSi), 3.23 (3H, s, OCH₃), 3.40, 3.42 (2H, d, SiCH₂O), 3.77 (1H, m, SiH).
²⁹Si NMR (C₆D₆): δ -129.2 (quaternary silicon), -77.0 (SiCH₂), -68.6 (SiH), -10.4, 11.0 (d, (Me₃Si)₂Si), -9.0 (Me₃Si)₃Si. MS(CI): m/e 510 (M⁺), 495 (M⁺ - Me), 437 (M⁺ - Me₃Si), 406 (M⁺ - Me₃SiOMe). HRMS: calcd for C₁₈H₅₄OSi₈, m/z 510.2372; found, m/z 706.3349.

CH₃OCH₂Si(SiMe₃)₂SiMe₂Si(SiMe₃)₃ (obtained from **6d**).
¹H NMR (CDCl₃): δ 0.18 (18H, s, (Me₃Si)₂Si), 0.22 (27H, s, (Me₃Si)₃Si), 0.38 (6H, s, Me₂Si), 3.21 (3H, s, OCH₃), 3.41 (2H, s, SiCH₂). HRMS: calcd for C₁₉H₅₆OSi₈ (M⁺ - Me) m/z 509.2230, found m/z 509.2280. MS (EI): 451 (M⁺ - Me₃Si), 420 (M⁺ - Me₃SiOMe).

X-ray Structure Analysis of 4. A prismatic colorless crystal of **4** was coated with Nujol and mounted in a thin-walled glass capillary. The data were collected on a Siemens P4 diffractometer with graphite-monochromated Mo K α radiation ($\lambda = 0.710$ 69 Å). Final unit-cell parameters for the

 a w $R2=\{\sum[w(F_o{}^2-F_c{}^2)^2]/\sum[w(F_o{}^2)^2]\}^{1/2}$ with $w^{-1}=\sigma^2(F_o{}^2)+(0.0603\,P)^2$ and $P=0.33333\max(0,F_o{}^2)+0.66667\,F_c{}^2.$ $R1=\sum(|F_o|-|F_c||)/\sum|F_o|.$ Gof = $\{\sum[w(F_o{}^2-F_c{}^2)^2]/(N_o-N_p)\}^{1/2}.$

complex were obtained by least-squares analysis of setting angles for 30 reflections, $22 < 2\theta < 27^\circ$. The intensities of two standard reflections were measured every 98 reflections during the data collection. The data were corrected for decay as well as for Lorenz and polarization effects. Pertinent crystallographic and experimental parameters for compound 4 are summarized in Table 4. After location of all silicon atoms by direct methods the full structure was derived by conventional electron density methods and was refined by full-matrix least-squares methods based on F^2 , minimizing the function $\sum [w(F_0{}^2 - F_c{}^2)^2]$. Hydrogen atoms were refined at ideal positions with groupwise relaxed C-H distances and isotropic displacement parameters. Non-hydrogen atoms were refined with anisotropic thermal parameters. Finally, a correction for

secondary extinction was applied. All calculations were performed with the programs SHELXS86 and SHELXL93 using the internal scattering factors. Selected bond lengths and angles are listed in Table 3. A view of the molecular structure of 4 is shown in Figure 1. Final positional and equivalent isotropic thermal parameters are given in the Supporting Information.

Acknowledgment. This research was partially supported by the Israel Science Foundation administrated by the Israel Academy of Science, by the German Federal Ministry of Science, Research, Technology, and Education (BMBF), and the Minerva Foundation and by the Technion VPR Fund for the Promotion of Research. D.B.-Z. is grateful to the Ministry of Immigrant Absorption, State of Israel, for a Gilhadi scholarship.

Supporting Information Available: A table giving atomic coordinates and equivalent isotropic displacement parameters for **4** and a figure of the unit cell of **4** (4 pages). Ordering information is given on any current masthead page.
